## **Abstract**

This study aims to examine the relationship between credit risk and capital adequacy with Banking hedging of Islamic and Conventional Banks in Yemen. A sample of 4 Conventional Banks and 3 Islamic Banks used during the period of (2012-2017). Using Pearson Correlation and Regression Analysis, we conclude that there is a statistically significant relationship between credit risk and Banking hedging, and a strong statistically significant relationship between capital adequacy and Banking hedging of Yemeni Banks. Based on the type of bank, results indicate to a negative relationship but not statistical significance between the credit risk and Banking hedging of Conventional Banks, and there is a statistically significant relationship between credit risk and Banking hedging of Islamic Banks. Capital adequacy positively interacts with the Banking hedging in both Banks.

Keywords: Credit risk, Capital adequacy, Baking hedging, Yemen.

## **1. Introduction.**

Yemen, among Middle East countries, considered as the weakest country in terms of growth and development, as well as the Yemeni Banking sector is the lowest system compared to Middle Eastern countries, because of the successive crises that have passed and affected Yemen. However, dominant over the financial system, so that any failure in the Banking sector will impact on the entire economic sector of a country (Al mekhlafi et al., 2016). The Yemeni Banking sector has faced many crises, the most important of which was the bankruptcy of the National Bank in 2004 due to poor management and the inability to recover depositors' money. Many challenges hindered

the improvement of the Yemeni Banking sector, such as the large size of non-performing loans and the weak implementation of regulatory standards. However, Yemeni Financial and Banking Sector evolved in the last decade, and this development accompanied by a set of reforms undertaken by the Central Bank of Yemen to raise the level of the Banking sector in several areas including organizational, supervisory, liquidity, and credit risk management, as well as enhancing capital adequacy requirements at the beginning of 2004 (**Shawtari et al., 2015**). Given this improvement of the Yemeni Banking sector, this improvement accompanied by an increase in growth and development of several Yemeni Banks, whether conventional or Islamic Banks as well as diversity and branching of their Banking activities, which led to rise in the risks facing Banks and impede the fulfilment of their obligations. Bearing to the mind that Yemeni Banks operate in an environment that lacks the controls that drive litigation procedures and enable Banks to recover their non-performing funds with others, and for this reason the possibility of risks accrue is high.

In light of the continuous changes in the economic environment, Banks face many risks, which the most critical risks are credit risk and capital risk. International Basel Committee concentrates on credit risk and capital risk because the losses that occur will cross beyond the Bank to impact the economic and financial system of the country, therefore the global economy through the dealings of other countries. Credit risk is the most crucial component of Banking risk as a whole, which contributes to more than 50% of the total Banking risk facing the Bank. Credit risk arises from the possibility that a borrower will not be able to meet its obligations on time, and that will affect the Bank's income and capital (**Lukic, 2015**). Also, given that Banks operate in a volatile environment that may expose them to risk, capital plays a significant role in helping Banks to face any unexpected losses. It also represents the most crucial element in the stability, safety, and security of Banks.

Islamic Banks differ from Conventional Banks in the possibility of exposure to risks due to the different nature and diversity of their business. **Kabir and Worthington (2015)** Indicated that according to the principles of Islamic Sharia under which Islamic Banks operate, that indicates for sharing risks during loss occurs, some Islamic financial products expose them to additional credit risk. Also, most studies believe that Conventional Banks have less credit risk than Islamic Banks (**Chong and Liu, 2009**). However, some reviews refer that the Conventional Banks are more

exposed to credit risk than Islamic Banks, where (How et al., 2005) argue that if there is a chance of losses, Islamic Banks have the option to share failures with depositors, while Conventional Banks don't have the same opportunity. Even, capital adequacy risk not less significant than credit risk, because it is considered as an essential defense line to the performance of Islamic Banks as they are for Conventional Banks (Karim et al. 2014). (Pellegrina, 2007) Believes that the minimum capital adequacy is inappropriate in Islamic Banks because the profit-loss sharing contract helps to reduce the overall risk of investment faced by the Bank. (Chowdhury, 2011), (Smolo, 2011) Add up to that capital adequacy is a source of safety for Islamic Banks, due to the nature of the risks faced by their Banking products and the kind of Islamic Banks as a mediator.

Moreover, many of the current studies focused on analyzing and examining the financial risks facing banks, in such a way to support the security level of Banks. Given that the importance of capital as an indicator to maintain the level of Banking security, and credit risk that global financial crises entail, in addition to what the International Settlements Bank indicated that Banks should define credit and capital risks accurately and measure them properly. Considering that studies on the Islamic Banking hedging and their comparison with Conventional Banks are few, thus, it is crucial to study credit risks and capital adequacy and compare their impact on the Banking hedging of Islamic and Conventional Banks. Therefore, this paper aims to determine the effect of credit risk and capital adequacy on Banking hedging of Islamic and Conventional Banks and set recommendations that help to raise the level of Banking hedging. The current study focuses on Yemen, considering that Yemeni Banks suffer from profound imbalances in their credit policies and capital adequacy, and suffer from the deficiencies in keeping pace with technical and technological developments. This study, as far as we know, is considered the first in Yemen that compares the impact of credit risks and capital adequacy on the Banking hedging of Yemeni Islamic and Conventional Banks.

The remainder of this paper was organized into the following: 2 Framework and Review of Literature, 3 Data, and Methodology, 4 Result and Discussion, 5 Conclusion.

## 2. Framework and Review of Literature

Banks face several types of risks, such as credit risk, capital adequacy risk, liquidity risk, interest rate risk, and operational risks, because of the rapid development of Banking transactions

and functions, big trend towards open economy, weak regulations and legislation related to banking business, the weakness of qualified cadres and other factors. Thus these risks may affect the performance of banks, profitability, and security, which led many researchers to study the risks and their impact on banks from several different dimensions whether performance, profitability, security, and others.

Accordingly, credit risk among all the types of risks consider as the biggest and the critical risks that face by Banks and Financial Intermediaries (Gray et al., 1997). Also, capital adequacy is highly significant and protects the Bank from Financing Leverage as well as keep banks away from the difficulties caused by insolvency and risk aversion (Nikhat,2014). This significant reflects the level of stability and security of the Financial and Banking System in any country. Therefore, as a result, these risks may impact Banking hedging- that consider as the precautions and caution against the risks that Commercial Banks are exposed to from their operational operations (Hempel, 1999) - either directly or indirectly. Thus, several empirical studies contribute to our prior understanding of credit risk and capital adequacy and their effect on Banking hedging.

## 2.1. Studies on Credit Risk

Credit is important for individuals and nations, and as the Banks are the main center for granting credit so it create a significant risk for the Banks (**Al-Gamal & Siddiq, 2019**). Therefore, several studies have compared the credit risk of Conventional and Islamic Banks in recent years. Most of these employed accounting-based techniques such as the distance-to-default, NPL and loan loss reserve ratios. To start, **Kabir et al. (2015)** evaluated the levels of credit risk in 37 Islamic and 156 Conventional Banks across 13 countries by using a market- based credit risk measure, and their result has shown that Islamic Banks have significantly lower credit risk than Conventional Banks. They argue that the method used for measuring credit risk plays an essential role in the level of measured credit risk. Nevertheless, **Mongi (2018)** argue that the Islamic Banks had significantly higher credit risk than the Conventional Banks when he applied country-level data of 17 Islamic Banks and 22 Conventional Banks in Malaysia based on generalized least squares (GLS). (**Pappas et al., 2012**) applied the survival analysis to compare the failure risk of the Islamic Banks and Conventional Banks, and found that the Islamic Banks have a significantly lower risk of failure than the Conventional Banks.

Credit risk considers as the most significant risk faced by Banks, and the success of Banks functions depends on accurate measurement and efficient management of this risk (**Gieseche, 2004**). However, credit risks if realized, it causes adverse effects that exceed the limits of the Bank to affect the financial system and the economy of the whole country. **Aezzki (2012)** reported the presence of the reverse influence of credit risk on the profitability of the Yemeni Commercial Banks of the level of each Bank or at the level of the Banks collectively. **Subsequently (Almekhlafi et al., 2016)** used credit risk, bank performance measures and macroeconomic indicators to examine the interaction between credit risk and Banks performance in Yemen, and they emphasize that non-performing loans shown a negative relationship with Banks profitability and performance and the high loan recovery cost associated to high credit risk exposure.

## **2.2. Studies on Capital Adequacy**

Capital plays a prominent role in facing potential risks in the event of insufficient allocations and reserves, and this is the reason that prompted the Central Banks to raise the Banks 'capital to provide an adequate margin of safety for depositors and stakeholders (**Saunders and Cornett, 2002**). Several studies discussed the issue of capital as (**Berger, 1995**), (**Altamimi and Obeidat, 2013**), (**Bokhari et al., 2013**), (**Rina and Yovin 2016**), (**Yuanjuan and Shishun, 2012**) (**Al Mekhlafi 2004**).

**Berge (1995)** examined the relationship between profitability and capital in American Commercial Banks by using regression analysis to analyze two periods (1983-1989) and (1990-1992) due to some changes in laws and regulations related to the Commercial Banks in American during these two periods. The result indicates that there was a strong positive relationship between profitability and capital during the first period when the capital was below the optimal level and an inverse relationship between profitability and capital when the capital was higher than the optimal level. Later (**Al Mekhlaf,2004**) examined the effect of indicators of the sufficiency of the capital adequacy in Bank risks and returns, and emphasized that the symbols of Banking risks and their profits are affected by the capital adequacy of the Bank's and that this will reflected in the banking value. (**Yuanjuan and Shishun, 2012**) measured the factors of capital adequacy in Chinese Banks, and they found that the return on assets positively proportional to the capital adequacy, and the liquidity and quality of assets are inversely proportional to the capital adequacy. And when (**Bokhari et al., 2013**) apply same analytical method on Pakistani Banks, reported that

return on equity, deposits and portfolio risks is inversely proportional to the capital adequacy, while the rest of the variables did not show any effect with the capital adequacy.

Also (**Altamimi and Obeidat, 2013**) investigate the factors that determine the degree of capital adequacy in Jordanian Commercial Banks and conclude that the degree of capital adequacy positively and significantly interacts with liquidity risk and the rate of return on assets. It interacts inversely and significantly with the rate of return on equity and interest rate risk. At the same time, there was no correlation between the degree of capital adequacy with capital risk, credit risk, and the rate of returns. Subsequent (**Rina and Yovin 2016**) concluded that capital risks affect performance in private banks, while credit risks affect the performance of the Government Banks by examining the impact of capital adequacy and additional factors on return on assets in Government and private Banks in Indonesia.

### **2.3. Studies on Banking Hedging**

Banking hedging studies linked to several dimensions that most important of these were liquidity risks, investment risks, capital risks, credit risk, interest rate risk in addition to independent variables related to the rate of return on equity and the rate of return of investment. **kharawish et al. (2004)** researched the factors that affect the level of Banking hedging in 13 selected Jordanians Banks, they used a financial analysis ratio based on multiple regression and reported that credit risk showed an Inverse relationship with Banking hedging; furthermore, return on equity and return on assets showed a Positive relationship with Banking hedging. In additional to that **Al ajlouni & alrgabat ( 2014)** emphasis that credit risk is the highest risk that impact on the Banking hedging, because of the late payment of the loan and interest in study that focused on examine the effects of Bank risks on the Jordanians Banking hedging, which results to the same findings of (**kharwish et al. 2004** ). Nevertheless, (**Omran,2015**) argues that capital risk is the most risk that impact the degree of Banking hedging and Credit risk didn't affect the degree of Banking security in Syria. But subsequent, **Al-afeef & al-Taani (2017)** based on the model developed by (**aljoluni & alrgaib ,2004**) found that there is an inverse relationship between credit risk and the degree of Banking hedging with no significant effect due to the irregularity of the criteria for the calculation of bad doubtful debts during the period of the study. , Furthermore, (**Amran ,2015**) and (**Sabah & shaheen, 2008**) used the financial analysis ratio based on regression analysis to examine the relationship between Banking hedging and risks, (**Amran ,2015**) reported that there is a negative

relationship between Credit risk and degree of Banking hedging of Nation Commercial Bank of Libya as well as (Sabah & shaheen , 2008) reached to the similar result in the Palestinian Banking sector.

Nevertheless (Alameen et al., 2014) argue that while Banking hedging positively interacts with capital risk, it does not show any interaction with credit risk; also capital adequacy has a positive relationship with capital risk and adverse relationship with credit risk. In an extension related to the current literature (khuyukah & Abdulrahman,2014) used data of Islamic Banks to build a measurement model to describe the degree of Banking hedging by evaluating and analyzing the indicators of the Banking statement and their impact on Banking hedging. The results support the idea of most of the previous studies that symbol to the inverse relationship between credit risk and degree of Banking hedging, and the positive correlation of capital adequacy and degree of Banking hedging.

According to the result of the previous studies of the effect of credit and capital risk on Banking hedging is still under debate, and the obtained results are diverging. In this respect, despite the existence of previous studies, we believe this study is an addition to the earlier studies because it includes investigating of the extent of influence and relationship between two groups of dependent variable (banking hedging) and independent variables (credit risk and capital risk) and the lack of studies that concern about the Islamic Banks and its comparison with the Conventional Banks in Banking hedging issue. So that a model will be specified to measure the degree of Banking hedging in Yemeni Islamic and Commercial Banks, Therefore, based on the foretasted theoretical developments to test the hypothesis that formulated as follow:

*H1. There is a statistically significant relationship between credit risk and Banking hedging.*

*H2. There is a statistically significant relationship between capital adequacy and Banking hedging.*

### 3. Data and Methodology

#### 3.1. Data Collection

This paper is limited to a homogeneous sample that includes the coverage of the Conventional Banks and Islamic Banks in Yemen. Because of the limited data, among the 17 Banks in Yemen, only seven Banks were chosen and included 4 Conventional Banks and 3 Islamic Banks during a period (2012-2017). Through the uses of databases for Banks themselves to analysis the annual reports, which almost was entirely available for the specific period, and this period represents the period that Yemeni Banks faced political and economic issues, which obliged the Banks to work better to increase Banking hedging. Data were collected form *CAC Bank, International Bank of Yemen, Yemeni Bank for Reconstruction and Development, Yemeni National Bank, Saba Islamic Bank, Bank of Yemen and Bahrain Shamil, Tahdamon International Islamic Bank*.

#### 3.2. Data Analysis

The main objectives of this study are to examine the effect of credit and capital risk on Banking hedging so that the theoretical framework for the study was developed based on previous reviews and books related to the study. In the practical aspect, the descriptive and analytical method used to describe, analyze and interpret the results to achieve the objectives of the study, which relied on the analysis of financial reports related to the study variables, where the particular financial ratios were calculated for independent and dependent changes for each Bank separately. Statistical methods were applied to achieve the objectives of the study and test the validity of its hypotheses such as the arithmetic mean, standard deviation and simple linear regression using the statistical package (SPSS).

Banking Hedging = shareholders / total assets or risky assets (1)

Credit Risk = risky assets / total assets (2) (Harawish et al., 2004)

Capital Adequacy = primary capital / risky assets (3)

, risky assets = long term loans + long term investment. (4) (Madura,2001).

#### 3.3. Descriptive Model

The model was built on the descriptive model, that was adopted by many researchers in clarifying the relation between the variables, therefore, the model to be tested is:

$$BH = \alpha_0 + \beta_1 * CR + \beta_2 * CA + \epsilon_i \quad (5)$$

Whereas:

BH: Banking Hedging , CR: Credit Risk. , CA: Capital adequacy

#### 4. Result and discussion.

##### 4.1. Result.

**Table (1) show descriptive statistics**

	N	Minimum			Maximum			Mean			Std. Deviation		
		con	isl	All	con	isl	all	con	isl	all	con	isl	all
<b>B.H</b>	42	.038	.047	.038	.132	.153	.153	.0843	.1008	.0914	.0271	.0364	.0321
<b>C.R</b>	42	.050	.375	.050	.180	.799	.799	.1096	.5837	.31278	.0403	.1168	.2510
<b>C.A</b>	42	.210	.075	.075	.830	.348	.830	.4893	.1919	.36185	.1550	.0931	.1981
<b>N</b>		24	18	42	24	18	42	24	18	42	24	18	42

This table displays descriptive statistics for the dependent variable and independent variables. It shows that the Minimum value for the dependent variable represented by banking hedging was (.038) while the Maximum value (.153) and the mean were (.09136) with a standard deviation equal to (.032079). For independence variables, the minimum value for the credit risk and capital adequacy was (.050) (.075) while the maximum value (.799) (.830), and the mean was (.31278) (.36185), with a standard deviation equal to (.250944) (.198122), respectively. However, the below table showed the descriptive statistics of Islamic and conventional Yemeni Banks.

**Table (2) show Pearson Correlation**

		Conventional			Islamic			All		
		B.H	C.R	C.A	B.H	C.R	C.A	B.H	C.R	C.A
B.H	Pearson Correlation Sig. (2-tailed) N	1			1			1		
C.R	Pearson Correlation Sig. (2-tailed) N	-.043- .842 24	1		.123 .627 18	1		.267 .087 42	1	

	Pearson Correlation Sig. (2-tailed)			1			1			1
C.A	N	.242	-.794		.808**	-.048		.075	-.772	
		.254	.000		.000	.849		.638	.000	
		24	24		18	18		42	42	

To begin the analysis of the relationship of credit risk and capital adequacy with the Banking hedging of Islamic and Conventional Banks, the Pearson correlation and linear regression to be used in this part of the analysis. It can be clear from the Table 2 that credit risk is weakly proportional with the banking hedging at a significant statistics level of (.087), and capital adequacy strongly proportional with the banking hedging at the level of significance (.638).

Based on the type of Bank, there is a significant difference in the relationship of credit risk and capital adequacy with the Banking hedging between Islamic and Conventional Banks. We reported there is an inverse relationship between the credit risk and Banking hedging of Conventional Banks at the level of significance (.842), capital adequacy showed a related relationship with the Banking hedging at the level of significance (.254). While Islamic Banks showed that credit risk is directly related to banking hedging at the level of significance (.627), and capital adequacy showed a strong and positive relationship with the Banking hedging at the level of significance (.000).

**Table (3) show Model Summary**

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.517 <sup>a</sup>	.267	.229	.028160

a. Predictors: (Constant), Capital Adequacy, Credit Risk

It is clear from Table 3 that the value of the determining factor (R square) of the Model is (.267) and it is considered a reasonably good value and indicates that the explanatory strength of the Model is good. It is showed that (%26.7) of the changes in the dependent variable (Banking hedging) are due to changes in Independent variables (credit risk, capital adequacy) and that (%73.3) of the changes in Banking hedging of Yemeni Banks is due to factors and other variables not included in the study. The errors estimated of (.028160) which is a small value and refer to the predictive ability of the Model.

This reasonably good indication of the model variables explains that although Yemeni Islamic Banks have achieved an excellent value for the factor (R square) of Model by (.680), which demonstrates (%68) of the changes in the dependent variable (banking hedging) in Islamic Banks due to changes in independent variables (credit risk, capital adequacy). Also, only (%32) from changes in the degree of Banking hedging in Islamic Banks due to other factors and variables not included in Model, and errors estimated of (.021918). But it is note that in conventional banks, the determination factor (R Square) equal to (.119), which indicates that only (% 11.9) of the changes in (banking hedging) in the Conventional Banks are due to changes in independent variables (credit risk and capital adequacy) and that the percentage (%88.1) is expected to changes in factors and variables not included in the study, also, the estimated errors (.026619).

**Table (4) show ANOVA**

Model	Sum of Squares	df	Mean Square	F	Sig.
Regression	.011	2	.006	7.103	.002 <sup>b</sup>
Residual	.031	39	.001		
Total	.042	41			

a. Dependent Variable: Banking Hedging

b. Predictors: (Constant), Capital Adequacy, Credit Risk

Table 4 shows ANOVA analysis of study variables, where the value of the coefficient ( $f = 7.103$ ) is considered reasonably good, and its degree of significant ( $\text{sig} = .002$ ) is less than (0.05), which indicates the significance of Fischer coefficient to test the importance of the model.

Based on the type of bank, there is a significant difference in Regression analysis between Islamic and Conventional Banks. Nevertheless, Islamic Banks are found that the value of the coefficient ( $f = 15.925$ ) and its degree of significant ( $\text{sig} = .000$ ) that is less than (0.05). In contrast, conventional banks are found that the value of the coefficient ( $f = 1.418$ ), and its degree of significant ( $\text{sig} = .265$ ) that is more than (0.05).

**Table (5) shown Coefficients<sup>a</sup>**

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
(Constant)	.018	.021		.899	.374
Credit Risk	.103	.028	.804	3.729	.001

Capital Adequacy	.113	.035	.696	3.226	.003
------------------	------	------	------	-------	------

a. Dependent Variable: Banking Hedging

Table 5 shows the regression coefficients of the model variables (credit risk and capital adequacy risk), results showed the coefficient t of credit risk is (3.729) at a significant level (sig = .001), which is smaller than (5%). But regarding the measure of the coefficient of capital adequacy (t = 3.729) at the level of significant (.003), which is smaller than (5%).

It notes from table 5 beta coefficient of the independent variables, which shows the value of the change that occurs in the dependent variable (Banking hedging) as a percentage at each difference in the independent variables that affect the dependent variable. Therefore, the beta coefficient shows that credit risk and capital adequacy impact on Banking hedging, but credit risk has a more significant effect, and its beta coefficient value (.804) and this explains that the degree of Banking hedging may change by (%80) when credit risk changes by (1%).

Based on the type of bank, there is a significant difference for Coefficients analysis between Islamic and conventional banks. Nevertheless, the coefficient t of credit risk of Islamic Banks is (1.111) at a significant level (sig = .284), which is more than (5%), and the coefficient t of capital adequacy (5.580) at a significant level (sig = .000), which is less than (5%). While the coefficient t of credit risk of Conventional Banks is (1.199) at a significant level (sig = .244) which is more than (5%), and the coefficient t of capital adequacy (1.671) at a significant level (sig = .110), which is more than (5%).

#### 4.2.Discussion.

According to Pearson Correlation credit risk is weakly proportional with the Banking hedging and capital adequacy strongly proportional with the Banking hedging, so that indicates that Yemeni Banks are working to maintain capital more than what was recommended by the Basel Committee for capital adequacy. Furthermore, Conventional Banks showed an inverse relationship between credit risk and Banking hedging, which indicate that Conventional Yemeni Banks did not expand in granting credit due to the reluctance of most Conventional Banks to invest in treasury bills of monetary nature and this result consistent with the findings of Al-Afeef & Al-Taani (2017). Also, capital adequacy showed a related relationship with the Banking hedging. While Islamic Banks showed that credit risk is directly related to Banking hedging, and capital adequacy showed a strong and positive relationship with the Banking hedging.

The determination factor (R Square) of the Yemeni Banks reasonably value and indicates that the explanatory strength of the model is good, and the errors estimated is small value and refer to the predictive ability of the model. Yemeni Islamic Banks showed an excellent value for the factor (R square) of the model, and this is clear from the results of the strong relationship between credit risk and capital adequacy with Banking hedging and errors estimated is small value and indicates the predictive ability of the model. The determination factor (R Square) of Conventional Banks is good but weak value, and the estimated errors are small value and indicate the predictive ability of the model.

Anova analysis indicates the significance of Fischer coefficient to test the significance of the model, and this means that the model has a statistical significance and gives a reasonably good degree of expectation and prediction of changes in the dependent variable (Banking hedging) depending on the changes in the independent variables. Based on the type of Bank, there is a significant difference in Regression analysis between Islamic and Conventional Banks. Nevertheless, Islamic Banks coefficient is considered strong, and its degree of significance is good, while Conventional Banks coefficient is considered week and its degree of relevance is week. Therefore, we reported that there is a statistical significance in Islamic Banks, and there is no statistical significance in Conventional Banks.

The regression coefficients show that credit risk is significant, and we accept the hypothesis that said there is a relationship between credit risk and Banking hedging. Also, capital adequacy is significant, and we recognize the hypothesis that said there is a relationship between capital adequacy and Banking hedging of Yemeni Banks. Based on the type of Bank, credit risk for Islamic Banks shown not significant and capital adequacy is significant, while credit risk of Conventional Bank shown not meaningful and capital adequacy not significant.

## **5. Conclusion.**

In this paper, the impact of credit risk and capital adequacy on Banking hedging of Islamic and Conventional Yemeni Banks investigated. A sample of 7 Banks - 4 Conventional and 3 Islamic - across the Yemeni Banking sector from (2012) to (2017 ). The descriptive and analytical method used to describe and analyze the results to achieve the objectives of the study through the analysis of financial reports related to the study variables, Where the particular financial ratios were calculated for independent and dependent changes for each bank separately and applied the accurate statistical methods.

The result showed that there is a statistically significant relationship between credit risk and Banking hedging, and a strong and statistically significant relationship between capital adequacy and Banking hedging of Yemeni Banks. Based on the type of bank, results show there is a negative relationship but not statistical significance between the credit risk and Banking hedging of the Conventional Banks, and there is a statistically significant relationship between credit risk and banking hedging of Islamic banks. Also, capital adequacy positively interacts with the banking hedging in both banks.

Moreover, the results indicate that the Yemeni Banking sector is still emerging and Conventional and Islamic Banks have a different view of risk. However, Conventional Banks do not grant credit significantly; Islamic Banks provide credit more through many credit products. It is also clear that Islamic Banks maintain capital adequacy, but that Conventional Banks maintain a high enough capital adequacy ratio. Consequently, the results of the study are essential for Policymakers, Academics, and Bankers.

Despite the limitations of this research and the lack of data, several recommendations identified. Conventional Banks should increase lending and not focused only on quasi-monetary and government securities and the need for Banks to follow the continuous development of regulatory and Banking controls of risk management, Banking safety. Besides, a balance should appear between Bank hedging with credit risk and capital adequacy risks. We suggest future studies to analyze the factors affecting the hedging of Islamic Banks in Yemen.
